

A 3x3 grid with a blue path starting at the top-left cell (0,0) and ending at the bottom-right cell (2,2). The path consists of the following cells: (0,0), (0,1), (1,1), (1,2), and (2,2). The cells (0,2), (1,0), and (2,0) are empty. The cells (0,1), (1,1), and (1,2) contain a grey 'X'. The cells (1,0) and (2,0) contain a grey circle.

Figure 1 consists of five box plots arranged in a 2x3 grid (with the last cell empty). Each plot shows the mean misclassification error for a specific dataset: Glass, Ionosphere, Sonar, Waveform, and an unlabeled dataset (likely a subset of the others). The y-axis for each plot represents the mean misclassification error, with scales varying by dataset. The x-axis for each plot lists five methods: t-part, t-part bagged, k-NN, k-NN bagged, and rf. The box plots illustrate the distribution of errors for each method. In general, the bagged versions of t-part and k-NN tend to have lower mean errors and narrower boxes (indicating less variance) compared to their single models. The rf method often shows higher error rates, particularly in the Sonar dataset where its error is significantly higher than the other methods.

- Understand for which kind of learners bagging can improve predictive power

- Understand for which kind of learners bagging can improve predictive power

BENCHMARK: RANDOM FOREST VS. (BAGGED) CART VS. (BAGGED) K-NN

- Goal: Compare performance of random forest against (bagged) stable and (bagged) unstable methods
- Algorithms:
 - classification tree (CART, implemented in `rpart`, `max.depth: 30`, `min.split: 20`, `cp: 0.01`)
 - bagged classification tree using 50 bagging iterations (`bagged.rpart`)
 - k-nearest neighbors (k-NN, implemented in `kknn`, $k = 7$)
 - bagged k-nearest neighbors using 50 bagging iterations (`bagged.knn`)
 - random forest with 50 trees (implemented in `randomForest`)
- Method to evaluate performance: 10-fold cross-validation
- Performance measure: mean misclassification error on test sets

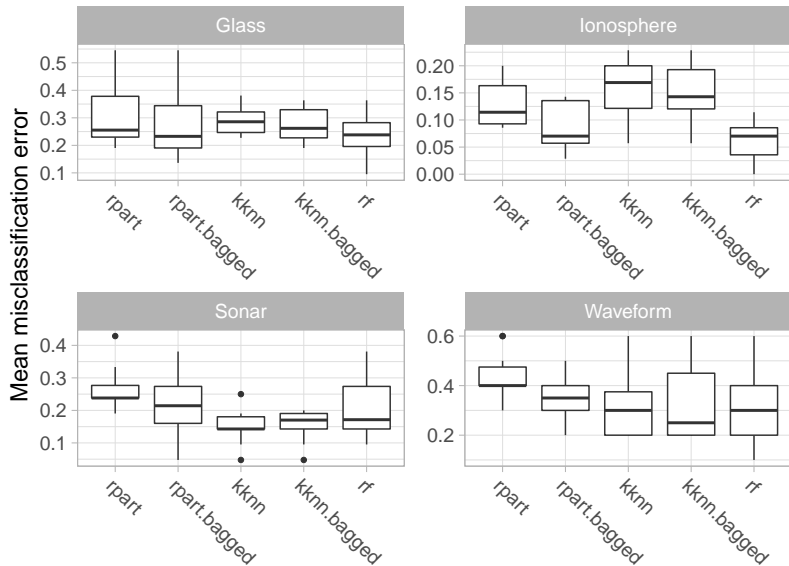

BENCHMARK: RANDOM FOREST VS. (BAGGED) CART VS. (BAGGED) K-NN / 2

- Datasets from **mlbench**:

Name	Kind of data	n	p	Task
Glass	Glass identification data	214	10	Predict the type of glass (6 levels) on the basis of the chemical analysis of the glasses represented by the 10 features
Ionosphere	Radar data	351	35	Predict whether the radar returns show evidence of some type of structure in the ionosphere (“good”) or not (“bad”)
Sonar	Sonar data	208	61	Discriminate between sonar signals bounced off a metal cylinder (“M”) and those bounced off a cylindrical rock (“R”)
Waveform	Artificial data	100	21	Simulated 3-class problem which is considered to be a difficult pattern recognition problem. Each class is generated by the waveform generator.

BENCHMARK: RANDOM FOREST VS. (BAGGED) CART VS. (BAGGED) K-NN / 3

BENCHMARK: RANDOM FOREST VS. (BAGGED) CART VS. (BAGGED) K-NN

Bagging k-NN does not improve performance because:

- k-NN is stable w.r.t. perturbations
- In a 2-class problem, nearest-neighbor-based classification only changes under bagging if both
 - the nearest neighbor in the learning set is **not** in at least half of the bootstrap samples, but the probability that any given observation is in the bootstrap sample is 63%, which is greater than 50%,
 - and, simultaneously, the *new* nearest neighbor(s) all have a different label than the missing nearest neighbor in those bootstrap samples, which is unlikely for most regions of $\mathcal{X} \times \mathcal{Y}$.
